

mucoide y aspecto brillante y, conformado por bacterias bacilares Gram-positivas sin disposición celular; y el morfotipo VP2, de colonias circulares beige mayores a 1mm de diámetro, elevación convexa baja, borde entero, superficie lisa, consistencia cremosa y aspecto brillante y, conformado por bacterias en forma de

coco, Gram-positivas sin disposición celular. Estos dos morfotipos bacterianos serán identificados a nivel de especie y actividad biológica en *V. planifolia*. Este trabajo representa un aporte importante al conocimiento de la comunidad microbiana asociada a las especies de *Vanilla* nativas de Colombia.

Extremely small orchid seeds lack endosperm, which is indispensable for seed germination. In nature the association with suitable mycorrhizal fungi provides simple sugars during the first steps of germination. Colombia is one of the countries with the greatest biodiversity of orchids, with an estimate of 3,200 species, but few studies on orchid mycorrhiza have been performed. In our study we isolated and sequenced the ITS rDNA region of fungi from two sympatric, epiphytic orchids of Colombia, *Ionopsis utricularioides* and *Psygmorechis pusilla*, both belonging to subtribe Oncidiinae. All sequences were recognized as belonging to the genus

*Ceratobasidium*, known to be a common orchid mycorrhizal fungus in both tropical and temperate orchids. One sequence was 100% similar to fungi isolated from *I. utricularioides* in Costa Rica in a previous study. *Ionopsis utricularioides* was confirmed to be a specialist, associating with only one clade of mycorrhizal fungi, whereas *Psygmorechis pusilla* proved to be a generalist, associating with three clades. This finding confirms that variation in mycorrhizal specificity is an important factor in co-existence of orchids. The high affinity between the subtribe Oncidiinae and *Ceratobasidium* was also confirmed.
